out one bank's position as that representing the entire economy. Summing up the vault cash and deposits at the Fed of the commercial bank where the city of Chicago maintains its working cash balances gives no information about the liquidity of the banking system of Chicago even if the city clearing house is maintained in the same bank.

The other IMF series, International Reserves, comes closer to the number needed to demonstrate the ability of the economy to meet an internal liquidity crisis (lender of the last resort) or the capability to expand the money supply or meet an excess of payments to foreigners over receipts from foreigners. The series is the sum of the same items that enter into Official International reserves but the aggregation is over the entire banking system. In addition, however, credit to non-residents is also included. Since alaredit is denominated in dollars, only the residence makes the loan international. Much of the movement in the series then reflects the oscillation of the international operations of the banking system, instead of an upper constraint on the banking system's expansionary forces of liquid assets. Both IMF series then are inadequate representations of the monetary base.

## APPENDIX B

# MONETARY STATISTICS

As in most other developing countries, statistics are a luxury in Panama. The high cost comes not so much from the use of precious tax revenue as from the large amounts of human capital consumed in collecting, categorizing and publishing the data. In addition, since most data collection activity is geared toward answering questions raised by international organizations with resources to spend, the type of numbers gathered emphasize standardization across countries rather than useful economic explanations of the economy. Finally, since Panama is a small country, it suffers from the "law of small" numbers where errors in classification by reporting agents can throw off the entire series since there is neither enough labor to verify all data collected, nor enough reporting agents to ensure the "errors average out."

This is especially true in the case of the banking sector data where the collected series serve adequately to answer the questions asked by the IMF, but do not necessarily describe the economics of the monetary situation, especially after the regional financial center began to develop. Consequently, since the published series was not always complete, contained the influence of interbank dealings throughout, and at times aggregated unpublished series in an arbitrary manner, it was necessary to utilize the original balance sheets collected by the Controleria General de la Republica and, after 1971, the Comision Bancaria. Unless otherwise stated, these balance

sheets served as the primary source for all monetary data. Tables 27 to 31 of this appendix contain the data series (aggregated across private and official banks) utilized in this dissertation and a brief description of how the series were aggregated. Because the disaggregations were not available, and the data less trustworthy, the data series for 1950-1959 used in Figure 1 are not reported. They were compiled from data presented in Table 34 of Compendio Estadistico 1950-59 published by Direccion de Planificacion de la Presidencia in the following manner:

Net Banking Credit: Local loans plus net other assets plus local investments less capital and reserves.

Liquid International Assets: "Effectivo" (cash) plus correspondent deposits less foreign deposit liabilities plus foreign investment.

Finally, although Panama mints coins, U.S. dollar bills circulate as local currency along with U.S. coins. Consequently, no figure is available as a measure of currency in the hands of the public. Several studies have attempted to estimate single year values of currency in the hands of the public, but none have tried a series. The Harberger estimate of 6-8 percent of GDP was utilized as a basis for the series. When compared to Nicaragua's currency to deposit ratio (averaging 75 percent), the values generated by 7 percent of GDP and by 75 percent of private deposits moved in a similar manner. The estimated series was modified in 1964 and 1968 to reflect banking runs, and then smoothed in 1965-67 and 1969 to reflect a gradual adjustment to the historical series. The 1971 and 1972 values were adjusted slightly to reflect abnormally high deposits in 1971, and the

Needs for External Financing for the <u>Development of Panama</u>, and Harberger,
"Reflections on the Monetary System of Panama."

run on the government savings bank in 1972. The resulting series and the end of year currency to deposit ratios are reported in Table 30. Note the falling trend as the public takes greater advantage of the developing banking system.

From 1973-II through 1974-IV, contains a correction for wholesale banking's impact on demand deposits in foreign banks, as three banks holding large deposits in foreign banks solely for wholesale banking purposes were eliminated from the consolidated account. The three began operations in 1973 and accounted for at least 50 percent and sometimes for more than 75 percent of the consolidated systems deposits in foreign banks.

Bank credit is the sum of net other local assets, local loans, and local "investments" held by the banking sector.

Adjusted bank credit nets out the capital and reserves accounts from bank credit.

CNet local bank credit removes the contribution of net endogenous foreign liabilities from adjusted bank credit.

Real money balances are calculated as the sum of private non-bank demand and savings deposits (average over the period) divided by the consumer price index (average over the period). The sum of demand and savings deposits is used to avoid the strong seasonal shifts between the two during the year.

### APPENDIX C

#### BALANCE OF PAYMENTS STATISTICS

The very openness of Panama's economy which allows her to be highly integrated into world goods and capital markets creates a statistical nightmare for anyone attempting to measure the capital accounts. In addition, there are the conceptual problems created by standardizing Panama's accounts with international agency requests. Such statistics let Panama be compared with other countries but do little for economic analysis (recording exports of oil under services, instead of goods, simply because they are sold to Panamanians who sell them to boats and planes instead of direct sales by refineries is one good example). The trade accounts used in Chapter V thus have replaced recorded fuel and lubricant imports by estimates of domestic consumption valued CIF at the refinery, and insurance and freight have been adjusted to remove the component attributable to fuelds and lubricants. Exports are thus understated by domestic value added at the refinery (mostly wages) which has been \$1-3 million a year. Factor service payments have been aggregated into their respective capital account figures so that increases in interest payments to foreigners and from foreigners resulting from the internationalization of the banking sector do not distort the domestic accounts.

Additional capital account problems arise due to the Colon Free Zone.

As the local banking center expanded, merchants in the Free Zone financed their warehouse inventories in Panama City Instead of New York. A survey

of banks revealed an unequal treatment of these loans with some banks classifying them as foreign, some as local loans. This complicates the normal developing country problem of unrecorded capital transactions showing up as errors and omissions. Again, balance of trade and capital account statistics must be taken with a grain of salt, since changes in end of period levels of reported outstanding foreign debt were used as indicators of the capital flows reported in Chapter V. Government accounts then are reasonably accurate, banking sector data less so, and private sector data may be off by as much as 100 percent in either direction. Nevertheless, they are still useful as indicators of the true flows, though shaky, indeed, for very exacting measurements. Those utilized in this dissertation were derived from the figures reported in Controleria General's Foreign Trade and Balance of Payments bulletins.

#### APPENDIX D

#### PRICE STATISTICS

Price statistics utilized were derived from the values reported in Controleria General's Price bulletin. In addition to the problems mentioned above in Chapter IV, the Panamanian wholesale price index suffers from some structural problems. The small size of the local market causes numerous items to be imported directly by one or two firms who serve the whole market, making a wholesale market unnecessary. Thus only one refinery imports all the crude oil, and the wholesale market is in gasoline and diesel oil. Some imported items never enter the index except to the extent they form part of the final good's price, while others enter under the domestic industrial sector after several stages of processing. One alteration of official data then was to move fuels from the domestic to the imported sector and to remove the impact of the fuel tax imposed in 1972.

To make the individual comparisons of the items of the wholesale price index, items in Panama's wholesale price index were re-grouped so as to be comparable with the U.S. classification. The weighting scheme was based on the share of the items in Panama's wholesale index, with the weights of each sub-index constructed summing up to one. The individual items are included on each chart.
